P93 III International Scientific and Technical Conference Named After V. Voyevodin “Problems of Modern Nuclear Power” (April 15 – 17, 2026, Kharkiv): Book of abstracts. Editor: Lytovchenko S.V.
Kyiv: Vistka LLC, 2026. – 108 p.

ISBN 978-617-8189-52-5

This book is the proceedings of the V. Voyevodin International Scientific and Technical Conference “Problems of Modern Nuclear Power”. The proceedings contain 64 abstracts. These materials present the studies of physical processes and phenomena in reactor materials and substances at different states under the influence of external factors, problems of the current state of nuclear energy, a stable and safe operation of nuclear power plants, storage of spent nuclearfuel, and related fields.

ORGINIZING COMMITTEE

Chair — academician of the National Academy of Sciences of Ukraine,
Azarenkov M.O.

Co-chair:

Volodymyr Kholosha — PhD in Economics, President of the Ukrainian Nuclear Society

Garkusha I.E. — academician of the National Academy of Sciences of Ukraine,

Danylo Lavrenov — First Vice President, Executive Secretary of the Ukrainian Nuclear Society

Sayenko S.Yu. — doctor of technical sciences, head of department of NSC KIPT,

Lytovchenko S.V. — doctor of technical sciences, head of the department of Reactor Engineering Materials and Physical Technologies of V.N. Karazin Kharkiv National University

Phylyp Kuznietsov — PhD in Physical and Mathematical Sciences, Director of the Educational and Scientific Institute “Faculty of Physics and Technology”, V.N. Karazin Kharkiv National University

Lobach K.V. — Ph.D., head of local organizing committee

Kuprin O.S. — Ph.D., deputy head

Levenets A.V. - academic secretary

Valeriy Zuiok — Ph.D. in Physical and Mathematical Sciences, Senior Research Fellow, Senior Researcher, NSC KIPT

Bohdan Mazilin — Ph.D., Lead Engineer, V. N. Karazin Kharkiv National University

Ihor Kolodii — Staff Member, NSC KIPT

ISBN 978-617-8189-52-5

UKRAINIAN NUCLEAR ENERGY: STRATEGIC RESOURCE IN THE FACE OF GLOBAL RESOURCE SHORTAGES

Today, the energy sectors of most countries are based on the coal and nuclear industries, with coal power being phased out while nuclear power continues to grow [1]. Given modern realities – such as population growth and the expansion of industry, infrastructure, cities, and engineering facilities – this process is expected to continue for years, and possibly decades, to come. Since the fuel and energy complex must be constantly maintained, improved, and expanded – particularly the electric power industry – the development and modernization of nuclear energy is not merely relevant, but a vital strategy for our country’s development in the near term. In 2021, Ukraine formulated the state program 'Critical and Strategic Mineral Resources of Ukraine in the Context of Globalization and Climate Change,' which provides a solid foundation for our country [2]. Given that our country has its own crystalline shield, which has been sufficiently geologically studied, one could say that the nuclear industry is fully supplied with radioactive raw materials. The shield rocks are responsible for the elevated concentrations of radioactive elements in our country. The problem is that these elements are associated with highly durable and ductile rocks, so their destruction and subsequent extraction are costly. On the other hand, there are areas within and around the shield itself where radioactive, rare earth, trace, and light elements are found in sediments and sedimentary rocks, making extraction from these elements significantly easier and more cost-effective. Let us examine these rocks in greater detail, as different scientific schools employ different classifications for them, and even sediments (such as sand, clay, etc.) are sometimes referred to as rocks. Our crystalline shield, composed of several large blocks, was formed approximately 2 billion years ago. Since then, peneplanation processes have significantly reduced its thickness. According to various estimates, its thickness has decreased by 2-3 km. Throughout this time, all eroded sediments were transported to the north, south, east, and west. Radioactive, rare-earth, rare, and other similar elements and minerals were transported along with them. Elements released during the transport process partially remained within detrital grains, partially formed organometallic compounds in coal matter, and partially remained in situ. Consequently, geologists have noted elevated concentrations of these strategic elements in the sediments covering the crystalline shield, as well as in the sediments and sedimentary rocks (including coal) surrounding the shield on all sides. In recent years, researchers at the Institute of Geotechnical Mechanics of the NAS of Ukraine have studied this issue in considerable detail, constructing schematic maps of the distribution of radioactive elements, germanium, zirconium, and other elements, in the hope that these findings will prove valuable to end-users [3].
